

AD8517/AD8527

FEATURES

Single Supply Operation: 1.8 V to 6 V
Space-Saving SOT-23, μ SOIC Packaging
Wide Bandwidth: 7 MHz @ 5 V
Low Offset Voltage: 3.5 mV Max
Rail-to-Rail Output Swing and Rail-to-Rail Input
8 V/ μ s Slew Rate
Only 900 μ A Supply Current, 1.8 V to 5 V

APPLICATIONS

Portable Communications
Portable Phones
Sensor Interface
Active Filters
PCMCIA Cards
ASIC Input Drivers
Wearable Computers
Battery-Powered Devices
New Generation Phones
Personal Digital Assistants

GENERAL DESCRIPTION

The AD8517 brings precision and bandwidth to the SOT-23-5 package even at single supply voltages as low as 1.8 V. The small package makes it possible to place the AD8517 next to sensors, reducing external noise pickup. The AD8527 dual amplifier is offered in the space-saving MSOP package.

The AD8517 and AD8527 are rail-to-rail input and output bipolar amplifiers with a gain bandwidth of 7 MHz and typical voltage offset of 1.3 mV from a 1.8 V supply. The low supply current makes these parts ideal for battery-powered applications. The 8 V/ μ s slew rate makes the AD8517/AD8527 a good match for driving ASIC inputs, such as voice codecs.

The AD8517/AD8527 is specified over the extended industrial (-40°C to $+125^{\circ}\text{C}$) temperature range. The AD8517 single is available in 5-lead SOT-23 surface-mount packages. The dual AD8527 is available in 8-lead SOIC and MSOP packages.

PIN CONFIGURATIONS

5-Lead SOT-23 (RT Suffix)

8-Lead SOIC (R Suffix)

8-Lead MSOP (RM Suffix)

NOTES

¹Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

²For supply voltages less than 6 V the input voltage is limited to less than or equal to the supply voltage.

Package Type	θ_{JA} ¹	θ_{JC}	Unit
5-Lead SOT-23 (RT)	230	146	$^\circ\text{C}/\text{W}$
8-Lead SOIC (R)	158	43	$^\circ\text{C}/\text{W}$
8-Lead μ SOIC (RM)	210	45	$^\circ\text{C}/\text{W}$

NOTE

¹ θ_{JA} is specified for worst-case conditions, i.e., θ_{JA} is specified for device soldered in circuit board for SOT-23 and SOIC packages.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD8517/AD8527 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The AD85x7 is a rail-to-rail operational amplifier that can operate at supply voltages as low as 1.8 V. This family is fabricated using Analog Devices' high-speed complementary bipolar process, also called XFCB. The process trench isolates each transistor to minimize parasitic capacitance thereby allowing high-speed performance. Figure 19 shows a simplified schematic of the AD85x7 family.

The input stage consists of two parallel complementary differential pair: one NPN pair (Q1 and Q2) and one PNP pair (Q3 and Q4). The voltage drops across R7, R8, R9, and R10 are kept low for rail-to-rail operation. The major gain stage of the op amp is a double-folded cascode consisting of transistors (Q5, Q6, Q8, and Q9). The output stage, which also operates rail-to-rail, is driven by Q14. The transistors Q13 and Q10 act as level-shifters to give more headroom during 1.8 V operation.

As the voltage at the base of Q13 increases, the V_{BE} of Q18 increases and starts to sink current. The opposite occurs during sourcing of Q20, the voltage at the base of Q13 decreases and the current source I8 feeds the output transistor via Q16, Q17, Q19, R13, and R14.

The output stage also furnishes gain, which depends on the load resistance, since the output transistors are in common emitter configuration. The output swing from each rail when sinking or sourcing 250 μ A is 35 mV from the rail.

The input bias current characteristics depend on the common-mode voltage, see Figure 10. As the input voltage reaches about 1 V below V_{CC} , the PNP pair (Q3 and Q4) turns off.

The 1 k Ω input resistor R1 and R2, together with the diodes D7 and D8, protect the input pairs against avalanche damage.

The AD85x7 family exhibits no phase reversal as the input signal exceeds the supply by more than 0.6 V. Excessive current will flow through the input pins via the ESD.

LOW VOLTAGE OPERATION

Battery Voltage Discharge

The AD8517 operates at supply voltages as low as 1.8 V. This amplifier is ideal for battery-powered applications since it can operate at the end of discharge voltage of most popular batteries. Table I lists the Nominal and End of Discharge Voltages of several typical batteries.

Figure 19. Simplified Schematic

Table I. Typical Battery Life Voltage Range

Battery	Nominal Voltage (V)	End of Voltage Discharge (V)
Lead-Acid	2	1.8
Lithium	2.6-3.6	1.7-2.4
NiMH	1.2	1
NiCd	1.2	1
Carbon-Zinc	1.5	1.1

RAIL-TO-RAIL INPUT AND OUTPUT

The AD8517 features an extraordinary rail-to-rail input and output with supply voltages as low as 1.8 V. With the amplifier's supply range set to 1.8 V, the common-mode voltage can be set to 1.8 V p-p, allowing the output to swing to both rails without clipping. Figure 20 shows a scope picture of both input and output taken at unity gain, with a frequency of 1 kHz, at $V_S = 1.8$ V and $V_{IN} = 1.8$ V p-p.

Figure 20. Rail-to-Rail Input Output

The rail-to-rail feature of the AD8517 can be observed over all voltage supply ranges for which the part is being specified, which is from 1.8 V to 5 V.

INPUT BIAS CONSIDERATION

The input bias current (I_B) is a nonideal, real-life parameter that affects all op amps. I_B can generate a somewhat significant offset voltage. This offset voltage is created by I_B when flowing through the negative feedback resistor R_F . If I_B is 500 nA (worst case), and R_F is 100 k Ω , the corresponding generated offset voltage is 50 mV ($V_{OS} = I_B \times R_F$).

Obviously the lower R_F the lower the generated voltage offset. Using a compensation resistor, R_B , as shown in Figure 21, can completely cancel this effect. With the input bias current canceled we still need to be aware of the input offset current (I_{OS}) which will generate a slight offset error. Figure 21 shows three different configurations to cancel I_B -induced offset errors.

Figure 21. Input Bias Cancellation Circuits

AD8517/AD8527

DRIVING CAPACITIVE LOAD

Gain vs. Capacitive Load

Most amplifiers have difficulty driving the capacitance load due to the higher currents required from the output stage for such loads. Higher capacitance at the output can increase the amount of overshoot and ringing in the amplifier's step response and could even affect the stability of the device. The value of capacitance load an amplifier can drive before oscillation varies with gain, supply voltage, input signal, temperature, and frequency, among others. Unity gain is the most challenging configuration for driving capacitance load. However, the AD8517 offers reasonably good capacitance driving ability. Table II shows the AD8517's ability to capacitance load at different gains before instability occurs. This table is good for all V_{SY} .

Table II. Gain and Capacitance Load

Gain	Max Capacitance
1	400 pF
2	1.5 nF
2.5	8 nF
3	Unconditionally Stable

In-the-Loop Compensation Technique for Driving Capacitance Loads

When driving capacitance loads in unity configuration, the in-the-loop compensation technique is recommended to avoid oscillation as is illustrated in Figure 22.

$$R_X = \frac{R_O R_G}{R_F} \quad \text{WHERE } R_O = \text{OPEN-LOOP OUTPUT RESISTANCE}$$

$$C_F = \left[1 + \left(\frac{1}{|A_{CL}|} \right) \right] \left(\frac{R_F + R_G}{R_F} \right) C_L R_O$$

Figure 22. In-the-Loop Compensation Technique for Driving Capacitance Loads

Snubber Network Compensation for Driving Capacitance Loads

As load capacitance increases, the overshoot and settling time will increase and the unity gain bandwidth of the device will decrease. Figure 23 shows an example of the AD8517 configured for unity gain and driving a 10 kΩ resistor and a 680 pF capacitor placed in parallel, with a square wave input set to a frequency of 250 kHz and unity gain.

Figure 23. Photo of a Ringing Square Wave

By connecting a series R-C from the output of the device to ground, known as the “snubber” network, this ringing and overshoot can be significantly reduced. Figure 24 shows the network setup, and Figure 25 shows the improvement of the output response with the “snubber” network added.

Figure 24. Snubber Network Compensation for Capacitive Loads

Figure 25. Photo of a Square Wave with the Snubber Network Compensation

The network operates in parallel with the load capacitor, C_L , and provides compensation for the added phase lag. The actual values of the network resistor and capacitor have to be empirically determined. Table III shows some values of snubber network for large capacitance load.

Table III. Snubber Network Values for Large Capacitive Loads

C_{LOAD}	R_x	C_x
680 pF	300 Ω	3 nF
1 nF	100 Ω	10 nF
10 nF	400 Ω	30 nF

TOTAL HARMONIC DISTORTION + NOISE

The AD85x7 family offers a low total harmonic distortion, which makes this amplifier ideal for audio applications. Figure 26 shows a graph of THD + N, for a $V_S > 3$ V the THD + N is about 0.001% and 0.03% for $V_S \geq 1.8$ V in a noninverting configuration with a gain of 1.

Figure 26. THD + N vs. Frequency Graph

A MICROPPOWER REFERENCE VOLTAGE GENERATOR

Many single supply circuits are configured with the circuit-biased to one-half of the supply voltage. In these cases, a false-ground reference can be created by using a voltage divider buffered by an amplifier. Figure 27 shows the schematic for such a circuit.

The two 1 M Ω resistors generate the reference voltages while drawing only 0.9 μ A of current from a 1.8 V supply. A capacitor connected from the inverting terminal to the output of the op amp provides compensation to allow for a bypass capacitor to be connected at the reference output. This bypass capacitor helps establish an ac ground for the reference output.

Figure 27. A Micropower Reference Voltage Generator

MICROPHONE PREAMPLIFIER

The AD8517 is ideal to use as a microphone preamplifier. Figure 28 shows this implementation.

Figure 28. A Microphone Preamplifier

The gain of the amplifier is set as $R3/R2$. $R1$ is used to bias an electret microphone and $C1$ blocks dc voltage from the amplifier.

Direct Access Arrangement for Telephone Line Interface

Figure 28 illustrates a 1.8 V transmit/receive telephone line interface for 600 Ω transmission systems. It allows full duplex transmission of signals on a transformer-coupled 600 Ω line in a differential manner. Amplifier A1 provides gain that can be adjusted to meet the modem output drive requirements. Both A1 and A2 are configured to apply the largest possible signal on a single supply to the transformer. Amplifier A3 is configured as a difference amplifier for two reasons: (1) It prevents the transmit signal from interfering with the receive signal and (2) it extracts the receive signal from the transmission line for amplification by A4. A4's gain can be adjusted in the same manner as A1's to meet the modem's input signal requirements. Standard resistor values permit the use of SIP (Single In-line Package) format resistor arrays. Couple this with the AD8517/AD8527's 5-lead SOT-23, 8-lead MSOP, and 8-lead SOIC footprint and this circuit offers a compact solution.

Figure 29. A Single-Supply Direct Access Arrangement for Modems

AD8517/AD8527

SPICE Model

The SPICE model for the AD8517 amplifier is available and can be downloaded from the Analog Devices' web site at <http://www.analog.com>. The macro-model accurately simulates a number of AD8517 parameters, including offset voltage, input common-mode range, and rail-to-rail output swing. The output voltage versus output current characteristics of the macro-model is

identical to the actual AD8517 performance, which is a critical feature with a rail-to-rail amplifier model. The model also accurately simulates many ac effects, such as gain-bandwidth product, phase margin, input voltage noise, CMRR and PSRR versus frequency, and transient response. Its high degree of model accuracy makes the AD8517 macro-model one of the most reliable and true-to-life models available for any amplifier.
